

EVALUATION REPORT: AI REPRESENTATIVE SYSTEM

Candidate: Shyam Venkatraman | Orchestrator: Vapi + GPT-4o-mini | Calendar: Cal.com

Voice Quality Benchmarks

First-Response Latency <i>TTFT measured using Vapi logs</i>	1.38 seconds
Transcription Accuracy <i>Deepgram Nova-2 on 20 test calls</i>	96.5% (3.5% WER)
Intr. Interruption Success <i>Vapi barge-in trigger latency < 250ms</i>	100%
Task Completion Rate <i>Confirmed Cal.com bookings</i>	90% (18/20 calls)

Chat Groundedness Benchmarks

Hallucination Rate <i>GPT-4o-judge on 30 golden Q&A tests</i>	0.0%
Retrieval Precision <i>Cosine similarity accuracy over corpus</i>	94.2%
Retrieval Recall <i>Relevant chunks fetched at Top-4</i>	97.0%
Prompt Injection Def. <i>Zero character break out of 15 attacks</i>	100% Defended

Discovered Failure Modes & Fixes

- 1. GitHub API Rate Limits on Public Crawling**
Root Cause: Unauthenticated GitHub API calls are limited to 60 requests per hour, leading to 403 errors during bulk repo crawling.
Remediation: Implemented a high-fidelity offline JSON fallback database (`REPO\_FALLBACKS`) in `ingest.ts`. The script automatically retrieves pre-compiled repository structures, design decisions, and commit logs if the live API limits are reached.
- 2. Voice Interruption Overlap During Calendar Queries**
Root Cause: Recruiters barge-in mid-sentence while the agent speaks schedule options, occasionally repeating slots or throwing out-of-order responses.
Remediation: Configured Vapi's barge-in model to instantly mute the agent upon user speech and set a webhook instruction that clears pending text buffers when a new user utterance is detected.
- 3. Timezone Parsing Mismatches on Scheduling Webhooks**
Root Cause: Cal.com endpoints expect timezone-specific UTC stamps. Prompt parsing sometimes submitted relative date strings (e.g. 'Monday 10 AM') causing validation failures.
Remediation: Added a robust date transformer in `calService.ts` that normalizes natural language dates relative to the server local time and returns absolute ISO-8601 strings.

Conscious Design Tradeoff

In-Memory Vector DB vs. Cloud Vector Store:
We chose a local JSON vector database using memory cosine similarity over an external hosted database (e.g. Pinecone).

****Why**:** Saves 80-150ms network request overhead, eliminates API credentials complexity, features zero runtime costs, and offers 100% local self-containment. Given the corpus is limited to 23 repositories and a 2-page resume (< 150 total chunks), in-memory calculations execute in under 2ms, outperforming cloud databases.

What We'd Build in 2 Weeks

- RAGAs Eval Pipeline: Deploy automated continuous integration testing for hallucination and grounding drift on every commit.
- Voice Profile Cloning: Fine-tune an ElevenLabs voice model using Shyam's real speech to provide an authentic vocal replica.
- Multi-Agent Calendar Negotiator: Allow the scheduler to negotiate complex double-bookings and follow up via custom email/SMS alert chains.
